Abstract : This approach is based on the mechanical characterization of a biomaterial which is an organiccomposite with a thermosetting polymer matrix reinforced with a glass fiber; this composite has beenproduced by a conventional casting method. Currently, composite polymer-matrix objects occupy animportant place in the aeronautics, automotive, medical industry etc....., for this purpose, we are interested in the study of a mechanical property of a thermosetting polymer matrix compositereinforced with glass fiber, this composite is intended for the orthopedic prosthesis of a tibia, this property called resilience. For so doing, we have realized a Charpy shock test on a sample of the polymer matrix composite reinforced with a glass fiber for the orthopedic prosthesis of a tibia. We have also supported this study by a hardness test and microscopic characterization (SEM) to reveal the microstructure of the composite.

Keywords : composite - mechanical property - resilience -hardness - microstructure
